ABSTRACT

Theory of Mind (ToM) refers to the ability to compute and attribute mental states to ourselves and other people. It is currently unclear whether ToM abilities are universal or whether they can be culturally influenced. To address this question, this research explored potential differences in engagement of ToM processes between two different cultures, Western (individualist) and Chinese (collectivist), using a sample of healthy adults. Participants completed a computerized false-belief task, in which they attributed beliefs to either themselves or another person, in a matched design, allowing direct comparison between 'Self' and 'Other' oriented conditions. Results revealed that both native-English speakers and native-Chinese individuals responded significantly faster to self-oriented than other-oriented questions. Results also showed that when a trial required a 'perspective-shift', participants from both cultures were slower to shift from Self-to-Other than from Other-to-Self. Results indicate that, despite differences in collectivism scores, culture does not influence task-performance, with similar results found for both Western and non-Western participants, suggesting core and potentially universal similarities in the ToM mechanism across these two cultures.

Key Words: Theory of Mind; Cross-Cultural; Perspective-Taking; False-Belief; Social Cognition

1.0 Introduction

A fundamental part of our day-to-day lives is our ability to understand, compute, and attribute mental states to both ourselves and other-people (Wimmer & Perner, 1983; McCleery, Surtees, Graham, Richards, & Apperly, 2011; Baron-Cohen, Leslie, & Frith, 1985). This ability is often referred to as possession of a 'Theory of Mind' (ToM), and plays an essential role in everyday communication, allowing us to understand what other people may believe, know, see, or think at any given time, and thus allowing efficient and successful interactions to occur (Premack & Woodruff, 1978; Apperly, 2013). Despite the key role of ToM, the nature and structure of the ToM mechanism, particularly in adults, currently remains unclear (Apperly, 2013; Apperly, Samson & Humphreys, 2005; Saxe, 2006). For instance, it is currently unclear whether ToM reflects universal processes, engaged and expressed in the same way regardless of cultural background, or whether ToM is subject to social influences, developing differently as a result of an individual's cultural experience (Shahaeian et al., 2014; Callaghan et al., 2005; Kobayashi, Glover, & Temple, 2006). The term 'culture' refers to key differences in social experiences, including, for example, styles of relating, social practices and values, geographical location, religious values, language, and diet (Chiao & Ambady, 2007; Markus, Kitayama, & Heiman, 1996; Adams et al., 2009). A number of prior studies have shown that clear cultural differences can be found across a wide variety of traits, including values, personality traits, visual perception, and spatial reasoning (Henrich et al., 2010; Hofstede, 2001; Arnett, 2008; Schwartz & Bilsky, 1990; McCrae & Terracciano, 2005; Nisbett et al., 2001). However, there is limited research that has examined cross-cultural differences in ToM processes in adults. By exploring the potential presence – or absence – of cross-cultural differences in adult ToM, we will be able to gain more insight into the structure of the ToM mechanism, such as the extent to which ToM processes may be considered universal versus culturally-influenced (e.g. Shahaeian, Nielsen, Peterson, & Slaughter, 2014; Rozin, 2003; Barrett et al., 2013; Sabbagh, Xu, Carlson, Moses & Lee, 2006).

Of the studies that have examined cross-cultural differences in ToM, a majority have focused on the *development* of ToM abilities (e.g. Shahaeian et al., 2014; Barrett et al., 2013; Sabbagh, Xu, Carlson, Moses & Lee, 2006; Callaghan et al., 2005; Liu, Wellman, Tardif, & Sabbagh, 2008; Wang et al., 2016). Results have revealed similar developmental trajectories of ToM abilities across a variety of cultures, suggesting that mentalistic reasoning (e.g., false-belief understanding) emerges at the same age, around 5-years-old, across different cultures (e.g. Callaghan et al., 2005; Avis & Harris, 1991; Sabbagh et al., 2006). However, despite this evidence of developmental synchrony in false-belief understanding, there is also evidence that suggests that certain aspects of ToM abilities (e.g.,

1
2
3 understanding of sarcasm) can be differentially enhanced across cultures, suggesting that cultural
4 background can influence the *sequence* in which ToM abilities emerge, whilst developing more
5 global mentalistic reasoning abilities (e.g. Vinden, 1996; Lecce & Hughes, 2010; Liu et al., 2008; Oh &
6 Lewis, 2008; Shahaiean, Peterson, Slaughter, & Wellman, 2011; Wellman et al., 2006; Mayer &
7 Trauble, 2013). For instance, Peterson et al. (2006) conducted a study with Australian and Iranian
8 children, aged 3-6-years old, examining separable ToM components, including understanding of
9 diverse beliefs (i.e., different people can hold different beliefs about the same thing) and knowledge
10 access (i.e., awareness that an individual may be ignorant or knowledgeable about a situation).
11 Results revealed no significant difference in overall ToM performance (i.e., scores taken as an overall
12 indicator of performance, across the tasks), but found that Australian children developed diverse
13 belief understanding *before* developing knowledge/ignorance understanding, whilst Iranian children
14 developed knowledge/ignorance understanding before diverse belief understanding, suggesting
15 cultural differences in the sequence of ToM emergence across these two populations (Peterson et
16 al., 2006). Further supporting this, Peterson and Siegal (1997) note that social experiences during an
17 individuals' development could greatly impact their ability to reason about others' minds; for
18 instance, it has been suggested that growing up with siblings may be associated with enhanced
19 false-belief understanding in young children (Perner, Ruffman, & Leekam, 1994; Liu et al., 2008).
20 Chinese children are more likely to be an only child than their American counterparts, and ToM
21 development and experiences may therefore greatly differ between Chinese and Western children
22 based not only on culture, but also on the social experiences that are a result of the cultural
23 experience. Whilst these studies with children have indicated the presence of at least some cultural
24 variation in ToM abilities, there is limited research that has directly compared fully-developed,
25 mature ToM capacities of adults across cultures.

33
34
35
36
37
38
39
40
41 One exception is a study conducted by Kobayashi, Glover, and Temple (2006), in which adult
42 participants (American English-speaking monolinguals and Japanese-English bilinguals) completed a
43 task whilst undergoing fMRI scanning. The task involved either ToM reasoning (i.e., attribution of a
44 belief), non-ToM reasoning (e.g., physical causal situations, such as identifying what a person can see
45 or hear), or reading of unlinked sentences (acting as a baseline condition). Results revealed that both
46 American and Japanese participants showed significant and comparable activation in the medial pre-
47 frontal cortex and anterior cingulate cortex when engaging in ToM processing, supporting prior
48 research findings (e.g. Ochsner et al., 2004; Mitchell, Banaji, & MacRae, 2005; Amodio & Frith,
49 2006). Interestingly, however, Japanese participants showed significantly less temporo-parietal
50 junction activity than American participants when engaging in ToM tasks, despite no significant
51
52
53
54
55
56
57
58
59
60

1
2
3 differences in behavioural performance between the two nationalities. Kobayashi et al. suggest that
4 these results may reflect potential cultural differences in the underlying neural bases of ToM, with a
5 reduced sense of Self/Other distinction present in the Japanese participants compared to American
6 participants, due to a larger emphasis on 'collectivist' traits compared to 'individualist' traits when
7 engaging in social contexts for the Japanese participants (Kobayashi & Temple, 2009; Kobayashi et
8 al., 2006; Perner & Aichhorn, 2008).

9
10
11
12
13 Supporting Kobayashi et al.'s (2006) conclusion, it has been argued that Western cultures (e.g.
14 United States, Canada, United Kingdom, and Australia) emphasize individuality and independence,
15 whereas non-Western cultures (e.g. Asian cultures) place more emphasis on interdependence and
16 sharing of group values (Nisbett, 2003; Nisbett & Masuda, 2003; Shahaieian et al., 2014; Nisbett,
17 Peng, Choi, & Norenzayan, 2001). Thus, if ToM is culturally-influenced, perhaps in non-Western
18 cultures, where interdependence is emphasized, there may be a reduced sense of the 'Self'/'Other'
19 distinction, whereas in Western cultures, where 'uniqueness' and individuality are encouraged, a
20 more distinct 'Self'/'Other' differentiation may be present (Kobayashi & Temple, 2009; Adams et al.,
21 2009; Naito, 2007; Naito & Koyama, 2006; Werner & Kaplan, 1963). A further study by Wu and
22 Keysar (2007) compared perspective-taking abilities of Chinese and American individuals, using a
23 communication game; their results revealed that Chinese participants were more efficient at taking
24 their communication partners' perspective than their American counterparts, suggesting that
25 Chinese individuals are more effective at considering the perspective of another person than
26 American individuals. However, it is noted that the participants in both Kobayashi et al.'s (2006) and
27 Wu and Keysar's (2007) study were all living in the United States, and the Chinese and Japanese
28 participants were bilingual, speaking fluent English; it is therefore unclear to what extent their
29 results may have been influenced by cultural experiences, as opposed to other outside influences.

41

42 To allow a direct measure of cultural differences, the study reported in this paper sought to explore
43 the extent to which Western (native-English speakers from the United Kingdom, United States, and
44 Canada, all tested in the U.K.) and non-Western participants (native Chinese individuals, tested in
45 China) differed on cultural dimensions of individualism and collectivism, and whether this influenced
46 performance on a ToM task, specifically selected to assess the Self/Other distinction. These two
47 cultures were selected as there is evidence to suggest a distinct differentiation between the two,
48 with China considered a more collectivist culture and Western cultures considered to be more
49 individualist (Morris & Peng, 1994; Chen, 2000; Oyserman, Coon, & Kimmelmeier, 2002). To ensure
50 results were reflective of two different cultures – that is, whether those in the participant sample
51

1
2
3 truly did differ in tendencies towards individualism and/or collectivism – a self-report questionnaire,
4 the Auckland Individualism and Collectivism Scale (AICS; Shulruf, Hattie & Dixon, 2007) was utilized,
5 directly assessing individualism and collectivism traits of participants. To assess ToM abilities,
6 participants completed a computerized false-belief task, the Self/Other Differentiation task, suitable
7 for use with adults (Bradford, Jentsch, & Gomez, 2015). The Self/Other Differentiation task allows
8 direct comparison of self-oriented and other-oriented belief-attribution processes, as well as the
9 role of ‘perspective-shifting’ in ToM.
10
11
12
13
14

15 The Self/Other Differentiation task has previously been used with Western samples, with results
16 demonstrating that in these samples, self-oriented processing is much more efficient (faster and
17 more accurate) than other-oriented processing (Bradford et al., 2015). Results have also shown a key
18 role of ‘perspective-shifting’ in ToM processing. Within the Self/Other Differentiation task,
19 participants are asked to solve dilemmas from either their own or another person’s perspective, in a
20 false-belief task scenario. Within a trial, participants may maintain a perspective (e.g., the ‘self’
21 perspective: ‘Where would you look?’ → ‘What did you think?’) or switch perspectives within a trial
22 (e.g., shifting from the ‘other’ perspective to the ‘self’ perspective: ‘Where would John look?’ →
23 ‘What did you think?’). Results from Western participants have demonstrated that the inclusion of a
24 perspective-shift within a trial (Self-to-Other or Other-to-Self) significantly influences responses
25 (taking longer and with more errors) than trials in which no perspective-shift is required (Self-to-Self
26 or Other-to-Other). Results have also shown that participants find it harder to shift from the ‘Self’
27 perspective to the ‘Other’ perspective within a trial (‘Where would you look?’ → ‘What did John
28 think?’) than they do to shift from the Other perspective to the Self perspective (‘Where would John
29 look?’ → ‘What did you think?’), suggesting that it is not only the need to shift perspectives that
30 influences response efficiency, but also the *type* of perspective-shift required (Bradford et al., 2015).
31 It is currently unclear whether these results – a differentiation between ‘Self’ and ‘Other’, and a key
32 role of perspective-shifting – are due to cultural influences on ToM abilities, perhaps reflecting an
33 individualist cultural background in which the ‘other’ is only considered when explicitly required, or
34 whether this reflects a universal component of the ToM mechanism, in which the ‘self’ acts as the
35 stem for understanding the ‘other’ perspective.
36
37
38
39
40
41
42
43
44
45
46
47
48
49

50 As discussed above, it has been suggested that in collectivist societies, consideration of the ‘other’
51 perspective may be regarded as equally important, if not more important, than consideration of the
52 ‘self’ perspective (Naito, 2007; Naito & Koyama, 2006; Wener & Kaplan, 1963; Oyserman et al.,
53 2002; Morris & Peng, 1994). If this is the case, and if ToM develops and is utilized differently as a
54
55
56
57
58
59
60

function of cultural-experience, it could be argued that there would be less of a differentiation between 'Self' and 'Other' for individuals from collectivist cultures, as the collectivist social experience may have reduced the differentiation between 'Self' and 'Other' in mentalizing processing, compared to individuals from individualist cultures (Shulruf et al., 2007; Adams et al., 2009; Kobayashi & Temple, 2009; Chen et al., 1998; Oyserman et al., 2002). Results from the Self/Other Differentiation task should, therefore, show no significant differences in behavioural responses (response times, error rates) to 'Self' versus 'Other' oriented belief-attribution questions, and no effect of perspective-shifting in efficiency of responses, for participants from collectivist cultures. However, if ToM abilities reflect universal traits, regardless of cultural experience, it would be expected that participants from both individualist and collectivist cultural backgrounds will show the same pattern of responses, with more efficient responses following 'Self' oriented belief-attribution (faster and more accurate) compared to 'Other' oriented belief-attribution questions, and a significant role of perspective-shifting (with trials requiring a perspective-shift taking longer, and being more error-prone, than trials that do not require a perspective-shift), as previously established in Western samples (Bradford et al., 2015).

2.0 Method

2.1 Participants

Fifty-five native-English speakers were recruited from St Andrews University, Scotland (34 females, 21 males; $M = 21.4$ years, range 17-34 years; participants all identified themselves as native-English speakers, from either the U.K., USA, or Canada). Fifty-four native-Chinese individuals were recruited from Peking University, China (35 females, 19 males; $M = 22.6$ years, range 18-28 years). A minimum sample size of 66 total participants was determined a-priori using G*Power software (Faul, Erdfelder, Lang, & Buchner, 2007); alpha was set at 0.05, and power at 90%, with an anticipated medium effect size ($f = .25$; Cohen, 1988). All participants were reimbursed for their time, at the standard rate for each institution (£5 per hour for St Andrews University; 25 Chinese Yuan or course credits at Peking University). Participants did not have any learning or reading disabilities. All participants gave informed consent and this study was approved for use in human subjects in accordance with the University of St Andrews Research Ethics committee.

2.2. Stimuli and Procedure

The tasks reported here were part of a battery of tasks completed in a single session, lasting no more than 60 minutes. All tasks were separated by a break in the session. **The AICS questionnaire** was always completed at the end of the testing session; the order of the computerised tasks was

1
2
3 randomized across participants. The task was presented on a 12-inch Laptop, with all participants
4 completing the tasks using the same apparatus.
5
6

7 **2.2.1 Auckland Individualism and Collectivism Scale (AICS)**

9 The AICS questionnaire, developed by Shulruf, Hattie, and Dixon (2007; see also Shulruf et al., 2011)
10 consisted of thirty questions measuring three dimensions of individualism, and two dimensions of
11 collectivism. For individualism, the dimensions measured referred to: responsibility (acknowledging
12 responsibility for one's actions; e.g., *'Being able to take care of myself is a primary concern for me'*),
13 uniqueness (distinction of the self from the other; e.g., *'I enjoy being unique and different from*
14 *others'*), and competitiveness (prime interest in striving for one's own goals; e.g., *'Competition is the*
15 *law of nature'*). For collectivism, the dimensions referred to: advice (seeking advice from people
16 before making decisions; e.g., *'I discuss job or study related problems with my parents'*) and harmony
17 (avoidance of conflict; e.g., *'I sacrifice my self-interest for the benefit of the group'*). Each of these
18 dimensions was measured by responses to four questions; ten filler questions were also included in
19 the questionnaire, to reduce emphasis of the focus on collectivism/individualism dimensions.
20
21
22
23
24
25
26
27

28 Participants were provided with a paper version of the AICS questionnaire in their native language,
29 and were asked to read each statement carefully, rating how strongly they felt each statement
30 described themselves on a Likert-type scale of 1 (Never/Almost Never) to 5 (Always). There was a
31 maximum possible score of 60 for individualism traits, and a maximum possible score of 40 for
32 collectivist traits. The AICS questionnaire has been used across a number of different cultures,
33 including the U.K., China, Romania, Italy, and Portugal, and the reliability across cultures, and
34 between the specific factors of the questionnaire and their relationship to individualism and
35 collectivism, has been found to be high (e.g., Fu et al., 2010; Shulruf et al., 2007; Shulruf et al., 2011).
36 Individualism and collectivism were assessed using these two dimensions to explore differences
37 between Western and Chinese participants on each of these components separately; prior research
38 has demonstrated that individuals can show varying traits of both individualist and collectivist
39 tendencies (i.e., that individuals may be individualist and collectivist concurrently, such as self-reliant
40 non-competitors or interdependent competitors), rather than necessarily being either individualist
41 or collectivist (e.g., Green, Deschamps, & Páez, 2005; Shulruf et al., 2011; Tamis-LeMonda et al.,
42 2008). Thus, this study sought to assess the extent to which participants from the two target
43 cultures independently differed on measures of both individualist and collectivist traits.

49
50
51
52
53
54

55 **2.2.2 Self/Other Differentiation Task**

1
2
3 The Self/Other Differentiation Task (Bradford, Jentsch, & Gomez, 2015) was programmed using E-
4 Prime software. The task consisted of 8 practice trials, and 120 test trials (Table 1 details the number
5 of trials in each test condition). All trials followed the same format, with each trial consisting of three
6 stages: **Dilemma Stage → Contents Revelation Stage → Probe Stage**. Only test trials required belief-
7 attribution, with practice trials always referring to reality states. There were two language versions
8 of the task – English and Chinese. Native-English speakers all completed the English version of the
9 task, and native-Chinese individuals all completed the Chinese version of the task.
10
11
12
13

14
15 ---- Insert Table 1 about here ----
16
17

18 *Dilemma Stage* – this stage was used to establish a belief-state. A sentence was shown on the screen
19 asking participants to identify where either they (self-oriented) or someone else (other-oriented)
20 would look for a specific object. Three images were presented in a horizontal line, one of which was
21 the correct answer. Participants indicated their selection by pressing one of the arrow keys on the
22 laptop keyboard, corresponding to the location of the object (left side image ←, central image ↓, or
23 right side image →). Dilemma questions were shown alone for 1500 ms, before the image answer
24 options were also displayed, for a maximum of 5000 ms. If an incorrect selection was made, or there
25 was no response within this time limit, an ‘X’ was displayed for 1500 ms before the Dilemma reset
26 until the participant correctly passed the trial.
27
28
29
30
31
32
33

34 *Contents Revelation Stage* – this stage was used to create a true- or false-belief state for
35 participants. Contents of the selected container was revealed, and could be either expected (true-
36 belief) or unexpected (false-belief). Contents were shown for 2000 ms and no response was
37 required. Following Self or Other oriented dilemmas, half of each were followed by expected
38 contents, and half by unexpected contents.
39
40
41
42
43

44 *Probe Stage* – this stage was used to assess belief-attribution abilities. A sentence appeared on
45 screen asking participants to identify what either they themselves or another person believed to
46 have been in a container, before they saw inside. Answers were indicated by selection of one image
47 from three presented in a horizontal line, as in the Dilemma stage. The probe question was
48 displayed for 1500 ms before the three answer options were revealed. Image answer options were
49 displayed until response, or for a maximum of 8000 ms if no response was recorded. Distracter
50 questions were also included at the probe stage (e.g. ‘*What colour was the egg box?*’) to reduce
51 participant’s ability to anticipate the correct answer until after the probe question was presented.

---- Insert Figure 1 about here ----

The questions used in the English and Chinese version of the Self/Other Differentiation task referred to the same Dilemmas/Probes (i.e. seeking the same objects). For the English version of the task, sentences were matched across conditions in terms of length, structure and syntax so that each 'Self'-oriented sentence had a matched 'Other'-oriented sentence (e.g. *'What would [you/Jane] think was in the container, if [you/Jane] hadn't seen inside?'*). It is noted that sentences were not matched in this way for the Chinese version of the task, as the nature of differences in language style and structure meant this was not possible. However, given that the questions made the same referrals as the English questions (e.g. looking for specific objects/self and other perspectives), the manipulations in self/other orientation remained consistent, and therefore this was not anticipated to significantly influence the responses of Chinese participants. Figure 1 illustrates a single trial as it would have been seen in the English versus Chinese language versions of the task. Sentence translations for this task were completed by a bi-lingual Chinese native, who was living in the UK, but had spent at least 20 years living in China. To ensure accuracy of translations, a random cross-section of sentences were back-translated, confirming the reliability of translations.

3.0 Results

To ensure the homogeneity of the samples, one participant (English, female, 34 years old) was removed from all analysis, as they were over three standard deviations from the mean age of the sample. This resulted in a final sample for analysis of 54 Chinese individuals (35 females, 19 males; mean age 22.6 years, range 18-28 years) and 54 English individuals (33 females, 21 males; mean age 21.13 years, range 17 – 30 years).

3.1 Auckland Individualism and Collectivism Scale

For the AICS questionnaire, questions were divided into those regarding 'Individualism' (responsibility, uniqueness, and competitiveness) and those regarding 'Collectivism' (advice and harmony). For analysis, an overall individualism score (out of 60) and an overall collectivism score (out of 40) was calculated, by adding together the sum of responses in each condition; i.e. each question was answered on a scale of 1-5, thus providing a number value for each question answered. These scores were then compared between Chinese and Western participant samples, to assess for any differences between the two groups. One participant (English, male) was not included in analysis, due to a failure to complete the AICS in its entirety.

1
2
3 An independent samples t -test showed no significant difference between English and Chinese
4 participants' ratings of individualism, $t(105) = 0.83, p = .41$, with similar scores of individualism in
5 the Western ($M = 45.9; S.D. = 5.79$) and Chinese ($M = 46.8; S.D. = 5.04$) responses; this may reflect
6 that Chinese participants in this sample were recruited from an urban rather than a rural population.
7 An independent samples t -test did, however, show a significant difference in ratings of collectivism
8 between Western and Chinese participants, $t(105) = 3.99, p < .001, d = .87$, with higher agreement
9 with statements reflecting collectivist traits in Chinese participants ($M = 30.9; S.D. = 3.89$) than in
10 Western participants ($M = 27.7; S.D. = 4.29$). Figure 2 illustrates the relationship between scores in
11 the individualism and collectivism scales, for both Chinese and Western participants.
12

20
21
22

23 **3.2 Self/Other Differentiation Task**

24
25 In the Self/Other Differentiation task, participants had up to 8,000 ms to respond to probe questions
26 after potential answer options were presented. Due to the presence of outliers in the data, trials in
27 which RTs were higher than 3,000 ms were excluded from analysis, to ensure comparability of
28 results across nationalities. This resulted in removal of an average of 1.60 % of test trials for Chinese
29 participants, and 1.50 % trials for English participants. After these trials were removed from the raw
30 data, an average RT for each test condition of the Self/Other Differentiation task was calculated for
31 each participant.
32
33
34
35
36

37
38 Nine participants (six Chinese, three English) were removed from analysis as they made at least 50 %
39 errors in one or more test condition, suggesting a failure to engage with the task. This resulted in a
40 final sample size for analysis of 48 native Chinese participants (32 females, 16 males; $M = 22.45$
41 years, range 18 – 28 years), and 51 English participants (32 females, 19 males; $M = 21.29$ years,
42 range 17 – 30 years).
43
44
45
46

47 **3.2.1 Dilemma Stage**

48
49 A Repeated-Measures ANOVA with Dilemma Type (Self vs. Other) as a within-subject factor, and
50 Nationality (Chinese vs. English) as a between-subjects factor, revealed a significant main effect of
51 Dilemma Type ('Where would [you/John] look for the sugar?') for RT, $F(1, 97) = 13.39, p < .001, \eta_p^2 =$

1
2
3 Dilemma Type, $F(1, 97) = 16.63, p < .001, \eta_p^2 = .15$, with more errors made in self-oriented
4 dilemmas ($M = 2.40\%$ errors, $S.D. = 2.26\%$) than other-oriented dilemmas ($M = 1.60\%$ errors, $S.D. =$
5 1.65%).
6
7

8
9 There was a significant interaction between Dilemma Type and Nationality for Error Rates, $F(1, 97) =$
10 $22.86, p < .001, \eta_p^2 = .19$, and a trend towards significance for RT, $F(1, 97) = 3.19, p = .08, \eta_p^2 = .03$.
11 Post-hoc analysis using paired-samples t -tests with Bonferroni corrections revealed that this was
12 because, for Chinese participants, there was no significant difference in RT to Self versus Other-
13 Oriented Dilemma questions, $t(47) = -1.14, p = .26$, but there was a significant difference in Error
14 Rates, $t(47) = 4.97, p < .001, d = .82$, with more errors following the Self-Oriented Dilemma
15 questions ($M = 3.83\%$ errors, $S.D. = 2.30\%$) than the Other-Oriented Dilemma questions ($M = 2.10\%$
16 errors, $S.D. = 1.89\%$). The opposite was true for English participants, with paired-sample t -tests
17 revealing a significant difference in RT to Dilemma Questions, $t(50) = -4.63, p < .001, d = .32$, with
18 faster responses to Self-Oriented Dilemmas ($M = 1146$ ms, $S.D. = 213$ ms) than Other-Oriented
19 Dilemmas ($M = 1221$ ms, $S.D. = 241$ ms), but no significant difference in error rates between Self and
20 Other-Oriented Dilemma questions, $t(50) = -.72, p = .94$.

30 3.2.1 Probe Stage

31
32 Analysis of the probe question (e.g., 'What did [you/John] think was inside the container, before
33 seeing inside?') considered whether there was a shift in perspective between Dilemma Type and
34 Probe Type. For trials in which there was no perspective shift, trials would either address the self
35 (Self-Self) or other (Other-Other) at both the Dilemma and Probe stages. In perspective shift trials,
36 trials could either shift from Self-to-Other, or from Other-to-Self, across the Dilemma to Probe
37 stages. A 2 (Perspective Shift: No Shift vs. Shift) x 2 (Contents: Expected vs. Unexpected) x 2 (Probe:
38 Self vs. Other) Repeated-Measures ANOVA was conducted on RT and Error Rates, with Nationality
39 (Chinese vs. English-Speakers) as a between-subjects factor.
40
41
42
43
44
45

46 Results revealed a significant main effect of Probe Type for RT, $F(1, 97) = 51.59, p < .001, \eta_p^2 = .35$,
47 and Error Rates, $F(1, 97) = 24.33, p < .001, \eta_p^2 = .20$, with faster and more accurate responses
48 following self-oriented probes ($M = 794$ ms, $S.D. = 182$ ms; 5.48% errors, $S.D. = 5.02\%$) than other-
49 oriented probes ($M = 860$ ms, $S.D. = 204$ ms; 8.43% errors, $S.D. = 5.40\%$). There was a significant
50 effect of Contents Type on RT, $F(1, 97) = 11.09, p = .001, \eta_p^2 = .10$, and Error Rates, $F(1, 97) = 84.99$,
51 $p < .001, \eta_p^2 = .47$, with faster and more accurate responses following expected contents ($M = 808$
52
53
54
55
56
57
58
59
60

ms, $S.D.$ = 199 ms; 3.89% errors, $S.D.$ = 4.14%) than unexpected contents (M = 845 ms, $S.D.$ = 193 ms); 10.03% errors, $S.D.$ = 6.47%).

----Insert Figure 3 about here ----

Critically, there was also a significant interaction between Perspective Shifting and Probe Type for RT, $F(1, 97) = 4.26$, $p = .04$, $\eta_p^2 = .04$, and Error Rates, $F(1, 97) = 11.28$, $p = .001$, $\eta_p^2 = .10$. This was due to a larger Probe Type effect (Other Oriented Probes minus Self Oriented Probes) in perspective shift trials (89 ms; 4.62% errors) than in no-perspective shift trials (44 ms; 1.27% errors). Post-hoc analysis, with Bonferroni corrections, revealed that there was a significant difference between probe types for RT in both perspective-shift conditions, $t(98) = -5.97$, $p < .001$, $d = .21$, and in no-perspective shift conditions, $t(98) = -3.28$, $p = .002$, $d = .43$. For Error Rates, there was a significant difference in responses to Probe Questions in perspective-shift conditions, $t(98) = -6.32$, $p < .001$, $d = .77$, but not in the no perspective-shift conditions, $t(98) = -1.58$, $p = .24$. For response times, this interaction was not modulated by nationality, $F(1, 97) = .76$, $p = .39$, $\eta_p^2 = .008$, suggesting similar effects across both Chinese and Western participants. For error rates, there was a significant three-way interaction between Perspective Shifting, Probe Type, and Nationality, $F(1, 97) = 4.74$, $p = .03$, $\eta_p^2 = .05$. Post-hoc analysis demonstrated that this was due to the interaction between Perspective Shifting and Probe Type only being present in the error rates for the Chinese participants, $F(1, 47) = 13.45$, $p = .001$, $\eta_p^2 = .22$, and not for the Western participants, $F(1, 50) = .80$, $p = .38$, $\eta_p^2 = .02$. Figure 3 illustrates these findings.

There was a significant interaction between Perspective Shifting and Contents Type for RT, $F(1, 97) = 19.73$, $p < .001$, $\eta_p^2 = .17$, and error rates, $F(1, 97) = 5.84$, $p = .02$, $\eta_p^2 = .06$, due to a larger difference between Expected and Unexpected contents conditions in no-perspective shift trials (M = 76 ms; 7.39% errors) compared to perspective-shift trials (M = 3 ms; 4.93% errors). Finally, there was a significant interaction between Contents Type and Probe Type for RT, $F(1, 97) = 20.66$, $p < .001$, $\eta_p^2 = .18$, and for error rates, $F(1, 97) = 24.81$, $p < .001$, $\eta_p^2 = .20$, due to a larger difference between 'Self' and 'Other' probes following unexpected contents (M = 102 ms; 5.41% errors) compared to expected contents (M = 31 ms; 0.48% errors). No other effects were significant.

4.0 Discussion

The aim of this study was to examine potential cross-cultural differences in ToM processing by utilizing the Self/Other Differentiation task to explore whether performance of Western participants

1
2
3 (native English speakers) differed from that of Chinese participants, in terms of the extent of
4 differentiation between 'Self' and 'Other' and the ease in which an individual is able to shift between
5 perspectives of the 'Self' and 'Other'. Results revealed that for both Western and non-Western
6 individuals, self-oriented belief attribution (i.e., the Probe stage) was significantly faster and more
7 accurate than other-oriented belief-attribution. Importantly, results also demonstrated a significant
8 interaction between Perspective Shifting and Probe Type present across both the Western and
9 Chinese samples, suggesting a resilient presence of this effect; this interaction reflects that,
10 regardless of culture, participants found it harder (i.e., were slower) to complete trials in which a
11 perspective-shift was required across the Dilemma to Probe stage (Self-to-Other or Other-to-Self),
12 compared to trials in which no perspective-shift was required. Critically, the *type* of perspective shift
13 that was required influenced responses, with slower responses to trials in which the perspective
14 required a shift from Self-to-Other, as opposed to trials requiring a shift from Other-to-Self. Results
15 indicate a robust finding of the differential processing of the 'Self' and 'Other' and a key role of
16 perspective-shifting in ToM expression across two different cultures, Western and Chinese.

24
25

26 In the current study, we compared the responses of Chinese native individuals and a representative
27 Western sample, who were all native-English speakers. These two cultures were selected as
28 representative of vastly different cultural backgrounds, and in particular with predictions that these
29 two cultures would reflect differences in individualist and collectivist traits. A key strength of this
30 study is that, unlike prior studies that have started to explore cross-cultural differences in ToM
31 processes, a questionnaire that explicitly assessed individualistic/collectivist traits participants
32 associated as being relevant to themselves was included, to allow assessment of whether the two
33 samples really did differ in these traits. Results revealed no significant difference in the Chinese or
34 Western participants' ratings of individualist traits. However, results did reveal a significant
35 difference between Chinese and Western participants' ratings of collectivist traits; as expected,
36 Chinese participants scored more highly on these traits than Western participants, supporting prior
37 research suggestions that Chinese culture involves a more collectivist approach in day-to-day living
38 (e.g., Morris & Peng, 1994; Chen, 2000; Oyserman, Coon, & Kemmelmeier, 2002). The result of no
39 significant difference in individualistic traits may reflect where the samples were recruited from;
40 participants were all recruited through university samples, at either the University of St Andrews,
41 Scotland, or Peking University, China. It may be that the individuals attending Peking University have
42 been exposed to more Western culture, and thus may have different motivations and experiences
43 than if participants had been recruited from a non-university population; future research may
44 further explore this, assessing the influence of exposure to Western cultures (e.g., time spent
45

1
2
3 abroad) compared to individuals with no exposure to Western cultures, and differences between
4 university versus non-university populations. However, the differences found in collectivist
5 tendencies in the current study suggest that the AICS questionnaire was able to tap into certain
6 traits that are more strongly promoted in non-Western cultures, supporting collectivist tendencies
7 such as interdependence and sharing of group values, when compared to Western cultures. Given
8 these findings, it appears that this study provides a good basis for direct comparison of cultural
9 differences in false-belief task performance.
10
11
12
13
14

15 As previously discussed, it is currently unclear whether the underlying features of ToM reflect a
16 universal capacity which would be seen to be utilized and expressed similarly across different
17 cultures, or whether ToM develops differently as a result of cultural influences, with adaptations to
18 the ToM capacity as a result of social experiences (e.g. Kobayashi & Temple, 2009; Adams et al.,
19 2009; Barrett et al., 2013; Shahaieian et al., 2014; Callaghan et al., 2005; Liu et al, 2008). Despite
20 finding evidence to support the notion that Chinese participants associated with more collectivist
21 tendencies than Western participants, performance of both cultures was similar on the Self/Other
22 Differentiation task. Both Chinese and Western participants were faster and more accurate when
23 attributing beliefs to the 'Self' compared to the 'Other' at the probe stage of the Self/Other
24 Differentiation task (i.e., where understanding of a belief-state was required), and both groups of
25 participants found it harder to shift from Self-to-Other than from Other-to-Self. The finding that in
26 both the Western and non-Western samples the 'Self' perspective is processed more efficiently
27 when attributing beliefs – faster and more accurately – than the 'Other' perspective supports the
28 suggestion that the 'self' may act as a stem for understanding of the 'other', indicating an egocentric
29 bias in processing of ToM, that may be a core, universal component of the ToM mechanism
30 (Bradford et al., 2015; Kinderman, Dunbar, & Bentall, 2011; Keysars & Gazzola, 2007; Bodden et al.,
31 2010; Decety & Sommerville, 2003; Harari et al., 2010).
32
33
34
35
36
37
38
39
40
41
42
43

44 This notion is further supported by the interaction seen between perspective-shifting and probe
45 type, across the two cultural samples. This interaction reflects that participants, regardless of
46 cultural background, found it harder to complete trials in which there was a perspective-shift
47 compared to trials in which there was no perspective-shift and, critically, that participants found it
48 harder to shift from Self-to-Other than from Other-to-Self. It appears that, in trials in which the 'Self'
49 perspective was primed at the Dilemma Stage, no additional cognitive effort is exerted to consider
50 the 'Other' perspective until explicitly prompted to do so, at the Probe Stage; in contrast, in trials in
51 which the 'Other' perspective was primed at the Dilemma stage, participants were able to efficiently
52
53
54
55
56
57
58
59
60

1
2
3 process the 'Self' perspective when prompted at the Probe stage, suggesting the 'Self' may have
4 been considered and processed as a means of understanding the 'Other' perspective. This finding is
5 resilient to cultural experiences; despite being a member of a collectivist society, and indeed
6 reflecting this experience in assessment of association with collectivist traits in the current study,
7 Chinese participants did not show a reduced differentiation between 'Self' and 'Other' at a
8 behavioural level, suggesting this differentiation may be a core component of the ToM mechanism,
9 utilized in similar ways across different cultures.
10
11
12
13
14

15 It is noted that in the prior research that has explored cross-cultural ToM, there is evidence to
16 suggest that, whilst overall explicit measures of ToM abilities appear to reflect similar levels of
17 success in ToM engagement across different cultures, closer inspection of factors such as the
18 emergence of ToM abilities in children and the neural correlates of ToM expression in adults have
19 revealed key differences in cross-cultural samples (e.g. Kobayashi et al., 2006; Perner & Aichhorn,
20 2008). It is therefore possible that, whilst results in the current study show similar patterns of
21 behavioural outcomes, different strategies may be being utilized by individuals from different
22 cultures to achieve the same goals, in terms of attribution of beliefs to either the 'Self' or 'Other'.
23 The results of the current study provide preliminary evidence that association with either
24 individualist or collectivist cultural backgrounds does not influence basic aspects of ToM abilities;
25 even in a more collectivist, inter-group focused culture, there appears to remain a distinct
26 differentiation between the 'Self' and 'Other' perspectives, and switching between these two
27 perspectives carries behavioural consequences, differing dependent on the direction of the
28 perspective-shift required.
29
30
31
32
33
34
35
36
37
38

39 These results provide some of the first opportunities to directly compare ToM abilities across two
40 different cultures, Western and Chinese, using behavioural measures, whilst assessing the extent to
41 which the two cultures truly do differ in their sense of individualist/collectivist traits. One potential
42 issue with utilizing the Self/Other Differentiation task cross-culturally was that, in translating the
43 sentences, there was a chance that some of the meaning would be lost, and additionally, sentence
44 structure was not able to be matched in terms of length and syntax. However, analysis of the error
45 rates at the probe stage suggest that Chinese participants performed equally as well as Western
46 participants on the task, indicating that translation of sentences did not lead to less understanding
47 of the task. Further, error rates were overall very low, again suggesting the task was not harder for
48 the Chinese participants than the Western participants. However, it is noted that at the Dilemma
49 Stage of the Self/Other Differentiation task, there was a significant interaction between Dilemma
50
51
52
53
54
55
56
57
58
59
60

1
2
3 Type and Nationality for error rates, which may reflect that some of the scenarios presented at the
4 Dilemma stage were less familiar to the Chinese participants compared to the Western participants;
5 results showed that at this stage of the task, Chinese participants made more errors when
6 responding from the 'Self' perspective compared to the 'Other' perspective, although there was no
7 significant difference in the speed in which 'Self' and 'Other' dilemmas were answered. In contrast,
8 Western participants were faster at responding to 'Self' dilemmas compared to 'Other' dilemmas,
9 but showed no significant difference in error rates between these two conditions.
10
11
12
13
14

15 The role of the Dilemma stage in the Self/Other Differentiation task is to prompt participants to
16 adopt the perspective of another person, or to consider their own perspective; the Probe stage of
17 the task requires explicit consideration of *what* the mental states (i.e., belief-states) of either the self
18 or another person are, following a true- or false-belief scenario. The results in this study indicate
19 that when first adopting a particular perspective, either self or other (i.e., dilemma stage), cultural
20 experience can modulate the ease at which a perspective is adopted. However, once this
21 perspective has been ascertained and a trial commences, cultural background no longer influences
22 responses, suggesting that it is only when first adopting the perspective of another person (or
23 considering one's own mental states) that this cultural influence is seen. This is illustrated in the
24 dilemma stage results, where Chinese participants made more errors following self-oriented versus
25 other-oriented dilemma questions, although showed no significant difference in response times
26 between these trial types. We suggest that this is due to higher levels of association with collectivist
27 traits amongst the Chinese participants, and that this is highlighted when originally engaging in
28 consideration of another person's perspective, i.e., at the dilemma stage of a trial when adoption of
29 a perspective (self or other) is required. At the probe stage of the task, when explicit consideration
30 of another person's belief state is required, Chinese and Western participants perform in similar
31 ways; that is to say, whilst association with collectivist traits may aid Chinese participants in
32 considering the 'other' perspective at the Dilemma stage, once a perspective is primed at the
33 dilemma stage, Chinese participants do not then demonstrate an advantage compared to Western
34 participants in switching between the perspective of 'Self' and 'Other' at the probe stage, indicating
35 that this is not a general advantage of the collectivist experience.

50 **4.1 Conclusion**

51 The aim of this study was to directly compare ToM abilities between two different cultures: Western
52 (native English-speakers) and non-Western (native-Chinese). To ensure representative samples of
53 these two cultures, the AICS questionnaire was used, finding no significant difference in
54
55
56
57
58
59
60

1
2
3 individualism levels between participants, but finding Chinese participants to be significantly more in
4 agreement with collectivism traits than Western participants. Results from the Self/Other
5 Differentiation task, assessing belief-attribution abilities, revealed similar results found for both
6 Western and Chinese participants. Both cultures showed a distinct differentiation between 'Self' and
7
8 'Other', with trials in which the self-perspective was required promoting faster and more accurate
9
10 responses than trials in which the other-perspective was required. Critically, the interaction between
11
12 Perspective-Shifting and Probe Type was also present across Western and Chinese cultures,
13
14 suggesting a resilient effect of this requirement; participants all found it harder to shift perspectives
15
16 from Self-to-Other than from Other-to-Self, supporting the suggestion of the 'Self' acting as a stem
17
18 for understanding of the 'Other'. Considerations of potential cross-cultural differences are important
19
20 in psychological research, to assess the extent to which findings may relate to more universal traits,
21
22 or more specific traits influenced by social and cultural surroundings. The results of this study
23
24 support the idea of core similarities in the ToM mechanism across the two cultures studied. Further
25
26 research to explore the neural signatures underlying these behavioural results, and whether
27
28 different strategies for ToM expression are utilized across cultures, would help build an even more
29
30 informed understanding of how the ToM mechanism develops, functions, and is utilized in everyday
31
32 life.

Figure Captions

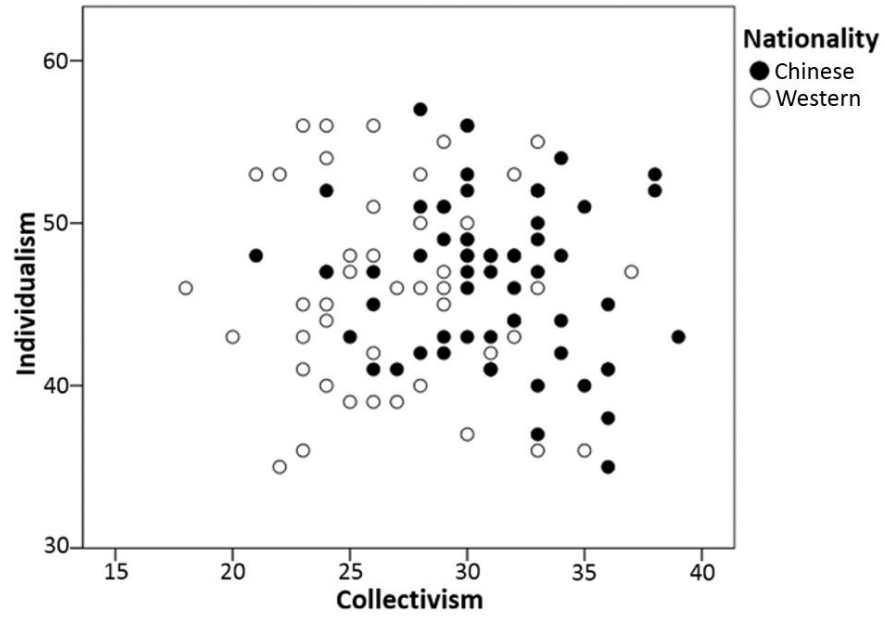

Figure 1: an illustration of a single trial (Self-Expected-Self) as it would have been seen in the English and Chinese versions of the task. All trials were translated from English to Chinese, so all participants were presented with the same dilemma and probe questions, to ensure comparability across the two different participant samples.

Figure 2: Scatterplot demonstrating the relationship between ratings on the individualism and collectivism traits in the AICS questionnaire, for Chinese and Western (native English speakers) participants.

Figure 3: The upper graphs illustrate mean response times (in ms), and the lower graphs present accuracy data (percentage of errors), for each test condition of the Self/Other Differentiation task. Mean responses are illustrated in the white bars for the Chinese participants, and the grey bars for the Western (native-English speakers) participants. Errors bars represent 95% confidence intervals.
